1 Introduction

A graph is an ordered pair $G = (V, E)$ where V is a non-empty set called the vertex set, whose elements are the vertices of G, and E is a set of unordered pairs of distinct vertices of G, whose elements are the edges of G. The order of G is its number of vertices and the size of G is its number of edges.

Two vertices u and v of G are adjacent, denoted by $u \sim v$, if $uv \in E$ (note that uv here denotes an unordered pair of vertices, and $uv = vu$). If there is no edge between u and v, then they are nonadjacent, denoted by $u \nsim v$. The vertex v and the edge uv are said to be incident with each other. The degree of a vertex v is the number of edges incident with it, or equivalently, the number of vertices adjacent with it, and is denoted by $\deg v$. The open neighbourhood (or simply neighbourhood) of a vertex v is the set of all vertices adjacent to v, and is denoted by $\mathrm{N}(v)$. Thus, $\deg v = |\mathrm{N}(v)|$. The closed neighbourhood of v is $\mathrm{N}[v] = \mathrm{N}(v) \cup \{v\}$.

Lemma 1.1 (Degree-Sum Formula)**.** *The sum of the degrees of all vertices of a graph is twice its size.*

Proof. Let G be a graph, and consider the sum of its degrees, $\sum_{v \in V(G)} \deg v$. As each edge is incident with exactly two vertices, each edge is counted once by two terms in this summation. Thus, the sum is equal to twice the number of edges. □

Corollary 1.2 (Handshaking Lemma)**.** *The number of vertices of odd degree in a graph is always even.*

Proof. Let G be a graph. We know that

$$\sum_{v \in V(G)} \deg v = 2|E(G)|. \tag{1}$$

Considering the vertices of odd and even degrees, we can write (1) as

$$\sum_{v \in V(G)\,:\,\deg v \text{ odd}} \deg v + \sum_{v \in V(G)\,:\,\deg v \text{ even}} \deg v = 2|E(G)|. \tag{2}$$

Both the RHS and the second term on the LHS are even integers, and therefore so is the first term on the LHS. But a sum of odd integers is even only if the number of terms is even. Thus, G has an even number of vertices of odd degree. □

The minimum degree of G is the $\delta(G) = \min_{v \in V(G)} \deg v$, and the maximum degree of G is $\Delta(G) = \max_{v \in V(G)}$. A regular graph is a graph in which all vertices have the same degree, or equivalently, if $\delta(G) = \Delta(G)$. This common value of the degree is the regularity of the graph. A regular graph of regularity k is a k-regular graph. A cubic graph is a 3-regular graph.

Exercise 1.1. Prove that if G is a graph of order n and size m, then $\delta(G) \leq 2\frac{m}{n} \leq \Delta(G)$.

Exercise 1.2. Show that if Γ is a finite group, then the number of elements of Γ that have centralisers of even orders is even.

Solution. Construct a graph G with the vertices of Γ as its elements, in which any two vertices x and y are adjacent if $xy = yx$ in Γ. Then observe that the centraliser $C_\Gamma(x)$ of x in Γ is $N[x]$, the closed neighbourhood of x in G. Hence, $|C_\Gamma(x)| = \deg_G(x) + 1$, which is even if and only if $\deg_G(x)$ is odd. Now the claimed statement follows from the Handshaking Lemma.

Theorem 1.3. *In any graph on two or more vertices, at least two vertices have the same degree.*

Proof. Let G be a graph of order $n \geq 2$. The minimum possible degree of a vertex of G is 0, and the maximum possible degree is $n - 1$ (as there are only n vertices in G). Thus, in order for the n vertices of G to have different degrees, the n different degrees must be exactly $0, 1, \ldots, n - 1$. But if some vertex of G has degree $n - 1$, then it is adjacent to all other vertices, and therefore G cannot have a vertex of degree 0. Thus, at least two vertices of G have the same degree. □

2 Subgraphs and Complements

A subgraph of a graph G is a graph H whose vertex and edge sets are, respectively, subsets of the vertex and edge sets of G – i.e. $V(H) \subseteq V(G)$ and $E(H) \subseteq E(G)$. A spanning subgraph of G is a subgraph containing all the vertices of G. A subgraph H of a graph G is an induced subgraph if for all vertices $u, v \in V(H)$, $uv \in E(H)$ whenever $uv \in E(G)$ – i.e. every edge of G that joins two vertices of H is present in H.

Example 2.1. Fig. 1 shows a graph G and three subgraphs H_1, H_2, and H_3 of G. The subgraph H_1 is neither a spanning subgraph (e.g. it does not contain v_3), nor an induced subgraph (e.g. it contains vertices v_2 and v_5 of G but not the edge $v_2 v_5$). H_2 is a spanning subgraph and H_3 is an induced subgraph of G.

Figure 1: A graph with three of its subgraphs

A graph is complete if all its vertices are adjacent to one another. The complete graph of order n is denoted by K_n. As there is an edge between every pair of distinct vertices of K_n, the size of K_n is $\binom{n}{2}$. The totally disconnected graph of order n, denoted by $\overline{K_n}$ is the graph of order n that has no edges.

The complement of a graph G is the graph $\overline{G}$ with the same vertices as G, in which any two vertices u and v are adjacent if and only if they are non-adjacent in G. Thus, if G is an (n, m)-graph, then $\overline{G}$ is an $\left(n, \binom{n}{2} - m\right)$-graph. Observe that $\overline{K_n}$ is (as the notation suggests) the complement of K_n.

Exercise 2.1. If G is a graph of order n, and $\deg_G v = k$, what is $\deg_{\overline{G}} v$?

Exercise 2.2. Show that if G and $\overline{G}$ are regular graphs of order n with the same regularity, then the regularity is even and $n = 4t + 1$ for some integer t.
3 Walks, Paths, and Cycles

A walk in a simple graph G is a sequence of vertices $v_1, v_2, \ldots, v_k$ such that $v_i \sim v_{i+1}$ for $i = 1, 2, \ldots, k - 1$ (we will hereafter omit the commas from the sequence). This is a walk from v_1 to v_k or between v_1 and v_k, having length $k - 1$. We may also say that this is a walk of length $k - 1$ starting at v_1 and ending at v_k.

A walk in which no vertex is repeated is a path. Note that the length of a path is the number of edges in it.

A closed walk in G is a walk starting and ending at the same vertex. A closed walk in which no vertex is repeated (except for its first and last vertices being the same) is a cycle. The length of a cycle is also equal to the number of vertices in it. A cycle of the form $v_1 \ldots v_{k-1} v_k$ is usually referred to as "the cycle $v_1 \ldots v_{k-1}$".

Example 3.1. Consider the graph G shown below.

A walk of length 5 from b to c in G is b, f, e, a, e, c.

This walk is not a path, since the vertex e is repeated. An example of a path from b to c in the same graph G is b, f, e, c. The length of this path is 3.

A cycle of length 4 in G is b, f, e, c, b.

7

If $P = v_1 \cdots v_k$ is a path from v_1 to v_k, we define $P[v_i, v_j] = v_i v_{i+1} \cdots v_j$, $1 \le i \le j \le k$, and $P(v_i, v_j) = v_{i+1} v_{i+2} \cdots v_{j-1}$, $1 \le i < j \le k$. If $Q = u_1 \cdots u_l$ is a path from u_1 to u_l, then we define $PQ = v_1 \cdots v_k u_1 \cdots u_l$. Note that PQ is a walk that may not be a path.

Theorem 3.2. *If $\delta(G) \ge 2$, then G contains a path of length $\delta(G)$ and a cycle of length greater than $\delta(G)$.*

Proof. Let $P = v_0 v_1 \cdots v_k$ be a longest path in G. Then all the neighbours of v_0 must be on P (for otherwise, we would get a path longer than P). Hence, $k \ge \deg v_0 \ge \delta(G)$.

Next, let $i \le k$ be maximal such that $v_i \sim v_0$. Then $v_0 \cdots v_i v_0$ is a cycle of length $i + 1$, and $i \ge \delta(G)$. $\qquad\square$

4 Distances

The distance between two vertices u and v of a graph G is the length of a shortest path between u and v – such a shortest path between u and v is a geodesic from u to v. Thus, the distance between u and v in G, denoted by $d_G(u, v)$ is the length of a geodesic from u to v in G. When the graph G is clear from the context, we will write $d_G(u, v)$ as $d(u, v)$.

The eccentricity of a vertex v, denoted by $\mathrm{ecc}(v)$, is the maximum of all distances from v to any other vertex. That is,

$$\mathrm{ecc}(v) = \max_{u \in V(G)} d(u, v).$$

The diameter of G is the maximum of the eccentricities of vertices of G, and the radius of G is the minimum of the eccentricities of vertices of G. They are denoted by $\mathrm{diam}(G)$ and $\mathrm{rad}(G)$ respectively. Thus,

$$\mathrm{diam}(G) = \max_{v \in V(G)} \mathrm{ecc}(v) = \max_{u,v \in V(G)} d(u,v)$$

$$\mathrm{rad}(G) = \min_{v \in V(G)} \mathrm{ecc}(v) = \min_{v \in V(G)} \max_{u \in V(G)} d(u,v).$$

The set of all vertices of G having minimum eccentricity, i.e. the set of all $v \in V(G)$ such that $\mathrm{ecc}\, v = \mathrm{rad}\, G$, is the centre of G.

5 Connectedness

A graph is connected if there is a path between every two of its vertices. Otherwise, it is disconnected. A (connected) component of a graph G is a maximal connected subgraph of G. Thus, a graph G is connected if and only if it has exactly one component.

Theorem 5.1. *For any graph G, either G or $\overline{G}$ is connected.*

Proof. Consider a graph G, and suppose that G is disconnected. We shall show that $\overline{G}$ is connected, by showing that there is a path between every two vertices of $\overline{G}$.

Let u and v be any two vertices of $\overline{G}$. If they are not adjacent in G, then they are adjacent in $\overline{G}$, and hence there is a path uv from u to v in $\overline{G}$. If u and v are adjacent in G, then they belong to the same component of G. As G is disconnected, it has at least one more component containing at least one vertex, say w, which is necessarily non-adjacent to both u and v. Hence, in $\overline{G}$, w is adjacent to both u and v. Thus, there is a path uwv from u to v in $\overline{G}$. Therefore, $\overline{G}$ is connected. □

Theorem 5.2. *For any connected graph G, if $\mathrm{diam}\, G \geq 3$, then $\mathrm{diam}\, \overline{G} \leq 3$.*

Proof. Consider a graph G of diameter at least 3. Then there exist vertices u and v in G such that $d_G(u,v) = 3$. This implies that u and v are non-adjacent in G, and hence adjacent in $\overline{G}$.

Now, consider any two vertices x and y other than u and v. In G, x can be adjacent to at most one of u and v, for otherwise, $d_G(u,v) = 2$. Hence, x is adjacent to at least one of u and v in $\overline{G}$. Similarly, y is adjacent to at least one of u and v in $\overline{G}$. Thus, there is a path of length at most 3 from x to y in $\overline{G}$ (namely xuy, xvy, $xuvy$, or $xvuy$), which implies that $d_{\overline{G}}(x,y) \le 3$. Therefore, $\operatorname{diam}\overline{G} \le 3$. □

Exercise 5.1. If G is a graph of order n and minimum degree $\delta(G) \ge \frac{n-1}{2}$, show that G is connected and $\operatorname{diam} G \le 2$.

6 Graph Isomorphism

An isomorphism from a graph G to a graph H is a bijective function $f : V(G) \to V(H)$ such for all vertices u and v of G, $u \sim_G v$ if and only if $f(u) \sim_H f(v)$. In other words, a graph isomorphism is a bijection from the vertex set of the first graph to that of the second, that preserves both edges and non-edges. If there exists an isomorphism from G to H, then G and H are isomorphic. Then we write $G \cong H$.

Isomorphic graphs have exactly the same structure – i.e. all properties of the graph that do not depend on the labelling or drawing will be shared by isomorphic graphs. For example, isomorphic graphs have the same order, size, degree sequence, diameter, and radius. Indeed, if f is an isomorphism from G to H, and v is a vertex of G, then the neighbours of $f(v)$ in H are the images of the neighbours of v in G, and $\deg_G v = \deg_H f(v)$. Similarly, if u and v are two vertices of G, then $d_G(u,v) = d_H(f(u), f(v))$.

Theorem 6.1. *Graph isomorphism is an equivalence relation on the class of all graphs.*

Proof. To show that graph isomorphism is an equivalence relation, we need to show that $\cong$ is a reflexive, symmetric, transitive relation between graphs. First, observe that the identity map on the vertex set of a graph is an isomorphism from the graph to itself – for, if G is a graph and id denotes the identity map on its vertex set then for any two vertices u and v of G, $u \sim v$ if and only if $\mathrm{id}(u) \sim \mathrm{id}(v)$, as $\mathrm{id}(u) = u$ and $\mathrm{id}(v) = v$. Hence, $\cong$ is reflexive.
Next, suppose that $G \cong H$. Then there exists an isomorphism f from G to H. Since $f \colon V(G) \to V(H)$ is bijective, it has an inverse $f^{-1} \colon V(H) \to V(G)$. We claim that f^{-1} is an isomorphism from H to G. We know that f^{-1} is bijective. To see that it preserves edges and non-edges, observe that if x and y are two vertices of H, then $x = f(f^{-1}(x))$ and $y = f(f^{-1}(y))$, which implies that $x \sim_H y$ if and only if $f^{-1}(x) \sim_G f^{-1}(y)$ (since f is an isomorphism from G to H). Therefore, f^{-1} is an isomorphism from H to G. This shows that $H \cong G$. Thus, $\cong$ is symmetric.

Finally, suppose that $G \cong H$ and $H \cong K$. Then there exist isomorphisms f from G to H and g from H to K. We claim that $g \circ f$ is an isomorphism from G to K. Indeed, $g \circ f$ is a function from $V(G)$ to $V(K)$, and being a composition of bijections, is itself a bijection. Now, suppose u and v are two vertices of G. Then $u \sim_G v$ if and only if $f(u) \sim_H f(v)$ (since f is an isomorphism from G to H) if and only if $g(f(u)) \sim_K g(f(v))$ (since g is an isomorphism from H to K). Thus, $g \circ f$ is an isomorphism from G to K. Therefore, $\cong$ is transitive. $\qquad\square$

7   Self-Complementary Graphs

A graph is self-complementary if it is isomorphic to its complement – i.e. G is self-complementary if $G \cong \overline{G}$. For example, K_1, P_4 and C_5 are self-complementary graphs of orders 1, 4, and 5 respectively. There is one more self-complementary graph of order 5, namely the bull graph, which can be constructed by adding one new vertex to P_4 and making

it adjacent to the two non-pendant vertices of the path. This graph is shown below.

Theorem 7.1. *The order of any self-complementary graph is $4k$ or $4k + 1$, for some non-negative integer k.*

Proof. Let G be a self-complementary graph of order n and size m. Then the size of $\overline{G}$ is $\binom{n}{2} - m$. Since $G \cong \overline{G}$, $m = \binom{n}{2} - m$, which implies that $m = \frac{1}{2}\binom{n}{2} = \frac{n(n-1)}{4}$. As m is an integer, this implies that 4 divides $n(n-1)$, which in turn implies that either one of n and $n - 1$ is divisible by 4, or both n and $n - 1$ are even. Since the latter is not possible, it follows that $n = 4k$ or $n - 1 = 4k$, i.e. $n = 4k$ or $4k + 1$ for some integer k. □

From Theorem 5.1, we know that a graph and its complement cannot both be disconnected. Thus, if G is a disconnected graph, then $\overline{G}$ must be connected, and therefore it cannot be isomorphic to G. This implies that a self-complementary graph is necessarily connected.

Corollary 7.2. *Every self-complementary graph is connected.* □

Similarly, from Theorem 5.2, we obtain the following corollary about the diameter of self-complementary graphs.

Corollary 7.3. *Every non-trivial self-complementary graph has diameter 2 or 3.*

Proof. Consider a non-trivial, self-complementary graph G, and suppose that it has diameter strictly greater than 3. Then, by Theorem 5.2, $\operatorname{diam} \overline{G} \leq 3$, which implies that $\operatorname{diam} \overline{G} \neq \operatorname{diam} G$, a contradiction, since $G \cong \overline{G}$. Hence, $\operatorname{diam} G \leq 3$. On the other hand, a non-trivial graph cannot have diameter 0, hence $\operatorname{diam} G \geq 1$. But if $\operatorname{diam} G = 1$, then G is a non-trivial complete graph, whose complement is a totally disconnected graph, which is again impossible. Hence, $\operatorname{diam} G = 2$ or 3. □

Exercise 7.1. If G is a regular self-complementary graph of order n, show that $n = 4k + 1$, for some integer k, and $\operatorname{diam} G = 2$.

Exercise 7.2. Let G be a self-complementary graph, and let H be the graph obtained by taking the disjoint union of H and P_4, and making every vertex of H adjacent to the two non-pendant vertices of this P_4. Then show that H is also self-complementary. What is the graph H obtained in this manner if $G = K_1$?

Exercise 7.3. Construct a self-complementary graph of order 9.

Exercise 7.4. Show that for each positive integer n of the form $4k$ or $4k + 1$, where k is an integer, there exists at least one self-complementary graph of order n.

8 Bipartite Graphs

A graph $G = (V, E)$ is bipartite if its vertex set V can be partitioned into two subsets V_1 and V_2 such that no two vertices in V_i are adjacent, for $i = 1, 2$. That is, there exist two non-empty, disjoint subsets $V_1, V_2 \subseteq V$ such that $V_1 \cup V_2 = V$, and every edge of G (if any) joins a vertex in V_1 with a vertex in V_2. Then we say that (V_1, V_2) is a bipartition of G.

The following theorem characterises bipartite graphs in terms of its cycles. A cycle is even if its length is even and odd if its length is odd.

Theorem 8.1. *A graph is bipartite if and only if it contains no odd cycles.*

Proof. First, suppose that G is a bipartite graph with bipartition (V_1, V_2), and let $v_1 v_2 \ldots v_k$ be a cycle of length k in G. Without loss of generality, suppose that $v_1 \in V_1$. Then, since $v_2 \sim v_1$, $v_2 \in V_2$, which in turn implies that $v_3 \in V_1$, as $v_2 \sim v_3$. Proceeding similarly, we see $v_i \in V_1$ if i is odd and $v_i \in V_2$ if i is even. But $v_k \sim v_1$ and $v_1 \in V_1$ implies that $v_k \in V_2$. Therefore, k (the length of the cycle) is even.

Conversely, suppose G is a graph that has no odd cycles. Without loss of generality, assume that G is connected – otherwise, apply the argument to each component. Let v be any vertex of G. Define subsets V_1 and V_2 of $V(G)$ as follows:

$$V_1 = \{\, u \in V \mid d(u, v) \text{ is even} \,\}$$
$$V_2 = \{\, u \in V \mid d(u, v) \text{ is odd} \,\}.$$

We claim that (V_1, V_2) is a bipartition of G.

Suppose not, and let x and y be adjacent vertices of G, both belonging to V_i for $i = 1$ or 2. Let P and Q be shortest paths from v to x and y respectively. Let w be the last vertex common to both P and Q when traversing P from v to x. Then the path $P[w, x]$, the edge (x, y), and the path $Q[y, w]$ form an odd cycle in G, which is a contradiction. Hence, (V_1, V_2) is a bipartition of G as claimed. $\qquad\square$

A complete bipartite graph is a bipartite graph in which every vertex of one partite set is adjacent to all the vertices of the other partite set. The complete bipartite graph with partite sets of cardinalities p and q is denoted by $K_{p,q}$.

Exercise 8.1. If G is a bipartite graph with bipartition (V_1, V_2), show that

$$\sum_{v \in V_1} \deg v = \sum_{v \in V_2} \deg v.$$

9 Trees

A tree is a connected, acyclic graph. There are several well known characterisations or alternative definitions of trees. We take the given definition as the basic one and prove its equivalence to some others.

Theorem 9.1. *A graph T is a tree if and only if there is a unique path joining every two vertices of T.*

Proof. First, suppose that T is a tree, and let u and v be vertices of T. Since T is connected, there is a path, say P, joining u and v. Now we must show that this path is unique. Assume to the contrary that there exists another path Q from u to v. When traversing P from u to v, let x be the first vertex common to P and Q such that its successor on P is not present on Q. Let y be the next vertex common to both P and Q when traversing P from x to v. Then $P[x, y]$ and $Q[x, y]$ together form a cycle in the tree T, which is a contradiction. Thus, P is the unique path joining u and v.

Conversely, suppose that T is a graph in which there is a unique path joining any two vertices. Clearly, T is connected. To show that T is acyclic, suppose that $v_1 v_2 \ldots v_n$ is a cycle in T. Then we get two different paths joining v_1 and v_n, namely the path $v_1 v_2 \ldots v_n$ and the path $v_1 v_n$ (since $v_1 \sim v_n$ in the cycle). This contradicts our assumption. Thus, T must be acyclic and hence is a tree. □

The next two results show that the size of a tree is always one less than its order, and that conversely, this property together with either connectedness or acyclicity implies that the graph is a tree.

Theorem 9.2. *A (p, q)-graph T is a tree if and only if it is connected and $p = q + 1$.*

Proof. Let T be a tree with p vertices and q edges. Then T is connected. We prove that $p = q + 1$ by induction. This is clearly true when $p = 1$.

Assume it to be true for all trees of order less than p. Now in T, we know that every two vertices are joined by a unique path. Thus, if e is any edge of T, then the graph $T - \{e\}$ obtained by deleting e has exactly two components, say T_1 and T_2. Each one is a tree, since it is connected and acyclic. Let T_i have p_i vertices and q_i edges, $i = 1, 2$. Then by the hypothesis, $p_i = q_i + 1$ (since $p_i < p$). But $p = p_1 + p_2$ and $q = q_1 + q_2 + 1$ (since the size of $T - \{e\}$ is one less than that of T). Thus, $p = q_1 + q_2 + 2 = q + 1$.

For the converse, suppose that T is a connected (p, q)-graph with $p = q + 1$. We must show that is acyclic. Suppose to the contrary that T has a cycle C with k vertices. Then C has k edges as well. Since T is connected, there is a path from every vertex not on C to some vertex of C. The shortest path from each vertex v not on C to a vertex on C has a unique edge incident with v, which is not part of C. Since there are $p - k$ vertices in T not on C, there are $p - k$ such edges. Thus $q \geq (p - k) + k = p$, which contradicts our assumption that $p = q + 1$. Thus, T must be acyclic. $\qquad\square$

In the following theorem, the proof of the direct part is identical to that of Theorem 9.2, except for the assertion being about acyclicity rather than connectedness. The proof of the converse part is entirely different.

Theorem 9.3. *A (p, q)-graph T is a tree if and only if it is acyclic and $p = q + 1$.*

Proof. Let T be a tree with p vertices and q edges. Then T is acyclic. We prove that $p = q + 1$ by induction. This is clearly true when $p = 1$. Assume it to be true for all trees of order less than p. Now in T, we know that every two vertices are joined by a unique path. Thus, if e is any edge of T, then the graph $T - \{e\}$ obtained by deleting e has exactly two components, say T_1 and T_2. Each one is a tree, since it is connected and acyclic. Let T_i have p_i vertices and q_i edges, $i = 1, 2$. Then by the hypothesis, $p_i = q_i + 1$ (since $p_i < p$). But $p = p_1 + p_2$ and

$q = q_1 + q_2 + 1$ (since the size of $T - \{e\}$ is one less than that of T). Thus, $p = q_1 + q_2 + 2 = q + 1$.

Conversely, suppose that T is an acyclic (p, q)-graph with $p = q+1$. To show that T is connected, we need to prove that it is connected – i.e. it has only one component. Let T have k components $T_1, \ldots, T_k$. Each one is acyclic, and being connected, is a tree. Thus from the first part of the theorem, we know that if p_i and q_i are respectively the order and size of the component T_i, $p_i = q_i + 1$. Now $p = p_1 + \cdots p_k = (q_1 + 1) + \cdots (q_k + 1) = q + k$. But we know that $p = q + 1$. Therefore, $k = 1$. Thus, T is a tree. □

Exercise 9.1. A pendant vertex of a graph is a vertex of degree 1. Prove that every non-trivial tree contains at least two pendant vertices.

Hint: Observe that a non-trivial tree cannot have a vertex of degree zero. Use Handshaking Lemma and assume every degree is at least 2 to get a contradiction.

Exercise 9.2. The centre of a graph G is the set of all vertices of G with minimum eccentricity – i.e. the set of all vertices v of G with $\operatorname{ecc} v = \operatorname{rad} v$. Show that every tree has a centre consisting of either exactly one vertex or exactly two adjacent vertices.

Hint: Observe that deleting all pendant vertices of a tree results in a new tree with the same centre.

Solution. Let T be a tree on n vertices. We prove the result by induction on n.

If $n = 1$ or 2, the result obviously holds. Suppose, for the sake of induction, that the result holds for all trees of order less than n.

Consider T, of order $n \geq 3$. Then T has at least two pendant vertices. Let T' be the tree (of order less than n) obtained by deleting all the pendant vertices of T.

Then the vertices of T' have eccentricities exactly one less than their eccentricities in T, and therefore, T and T' have the same centre. Hence, the result follows by induction.

10 Cartesian Product of Graphs

The Cartesian product of two graphs G and H is the graph denoted by $G \times H$, whose vertex set is $V(G) \times V(H)$, in which two vertices (u_1, v_1) and (u_2, v_2) are adjacent if and only if either $u_1 = u_2$ and $v_1 \sim v_2$ or $u_1 \sim u_2$ and $v_1 = v_2$.

Exercise 10.1. Prove that if G is a graph of order p_1 and size q_1, and H is a graph of order p_2 and size q_2, then $G \times H$ is a graph of order $p_1 p_2$ and size $p_1 q_2 + p_2 q_1$.

Solution. By definition, the vertex set of $G \times H$ is the Cartesian product $V(G) \times V(H)$ of the vertex sets of G and H, and therefore contains $|V(G)| \times |V(H)|$ elements. Thus, the order of $G \times H$ is $p_1 p_2$.

Now, consider any vertex (u, v) of $G \times H$. Corresponding to every vertex u' adjacent to u in G, there is an edge from (u, v) to $(u', v))$ in $G \times H$. Similarly, corresponding to every vertex v' adjacent to v in H, there is an edge from (u, v) from (u, v') in $G \times H$. Thus, the degree of (u, v) in $G \times H$ is $\deg u + \deg v$. Hence, by the Handshaking Lemma, the size of $G \times H$ is half the sum of its vertex degrees, which is

$$
\frac{1}{2} \sum_{u \in V(G), v \in V(H)} (\deg u + \deg v) = \frac{1}{2} \sum_{u \in V(G), v \in V(H)} \deg u + \frac{1}{2} \sum_{u \in V(G), v \in V(H)} \deg v
$$

$$
= p_2 \left(\frac{1}{2} \sum_{u \in V(G)} \deg u \right) + p_1 \left(\frac{1}{2} \sum_{v \in V(H)} \deg v \right)
$$

$$
= p_2 q_1 + p_1 q_2.
$$

Exercise 10.2. Show that if G is an r-regular graph and H is an s-regular graph, then $G \times H$ is a regular graph of regularity $r + s$.

11 Adjacency Matrices

The adjacency matrix of a graph G of order n, with vertex set $V = \{v_1, \ldots, v_n\}$, is the $n \times n$ matrix $A = A(G)$ whose (i, j)-entry is

$$a_{ij} = \begin{cases} 1, & v_i \sim v_j \\ 0, & v_i \nsim v_j. \end{cases}$$

Example 11.1. The adjacency matrix of the graph

is

$$A = \begin{bmatrix} 0 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \end{bmatrix}.$$

Observe that, as the graphs we discuss are simple graphs and therefore have no self-loops on vertices, no vertex is adjacent to itself – i.e. $a_{ii} = 0$ for all $i = 1, \ldots, n$. Also, since the graphs are undirected, $v_i \sim v_j$ if and only if $v_j \sim v_i$ – i.e. $a_{ij} = a_{ji}$. Thus, we have the following observation.

Observation 11.2. *The adjacency matrix of a (simple, undirected) graph is a symmetric, zero-diagonal, $(0, 1)$-matrix.*

In the ith row of the adjacency matrix, for each j, the jth entry is 1 if v_j is adjacent to v_i, and 0 otherwise. That is, the number of 1s in the ith row is the number of vertices adjacent to v_i, or in other words, the degree of v_i. Thus, the row sums of A are the vertex degrees. Observe that $A\mathbb{1}$ is the vector of row sums, where $\mathbb{1}$ is the vector (of suitable size) with all entries equal to 1. For instance, with the matrix A given in Theorem 11.1,

$$
A = \begin{bmatrix} 0 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 6 \\ 2 \\ 6 \\ 2 \\ 2 \\ 2 \\ 2 \end{bmatrix}.
$$

From the Handshaking Lemma and the preceding observation, it follows that the sum of all entries of A is twice the number of edges of the graph.

Exercise 11.1. Show that the (i, j)-entry of A^2 is the number of walks of length 2 from v_i to v_j. Hence show that $\operatorname{tr}(A^2) = 2|E(G)|$.

Hint: Recall that if A is any $n \times n$ matrix, then the (i, j)-entry of A^2 is $\sum_{k=1}^{n} a_{ik}a_{kj}$. As A is a $(0, 1)$-matrix, each term in this summation is 1 or 0, with the former if and only if $a_{ik} = a_{kj} = 1$. What does this imply about the vertices v_i, v_k, and v_j? Then, as k varies from 1 to n, what does the value of the sum imply about v_i and v_j?

The following result (which generalises the statement in Exercise 11.1) shows that the adjacency matrix can be used to obtain certain information about walks in the graph.

Theorem 11.3. *Let A be the adjacency matrix of a graph G with vertex set $\{v_1, \ldots, v_n\}$. Then the (i, j)-entry of A^m, for any positive integer m, is the number of walks of length m from v_i to v_j.*

Proof. We prove the result by induction on m. For $m = 1$, the (i, j)-entry of $A^1 = A$ is a_{ij}, which is 1 if and only if v_i is adjacent to v_j, i.e. if and only if there is a walk of length 1 (namely, an edge) from v_i to v_j. Thus, the result holds for $m = 1$.

Now suppose, for the sake of induction, that the result holds for some $m \geq 1$, and consider A^{m+1}. The (i, j)-entry of A^{m+1} is

$$(A^{m+1})_{ij} = \sum_{k=1}^{n} (A^m)_{ik} a_{kj}.$$

First, note that $a_{kj} = 1$ if and only if $v_k \sim v_j$. Therefore, the above sum is equal to the sum of all $(A^m)_{ik}$ where $v_k \sim v_j$. Now, by the induction hypothesis, $(A^m)_{ik}$ is the number of walks of length m from v_i to v_k. If v_k is adjacent to v_j, then each walk of length m from v_i to v_k, together with the edge from v_k to v_j, forms a walk of length $m + 1$ from v_i to v_j. Thus, for each k such that $v_k \sim v_j$, $(A^m)_{ik} a_{kj} = (A^m)_{ik}$ is the number of walks of length $m + 1$ from v_i to v_j that pass through k. Summing over all k, this gives the total number of walks of length $m + 1$ from v_i to v_j. Hence the result follows by induction. $\square$

Theorem 11.4. *Let A be the adjacency matrix of a graph G with vertex set $\{v_1, \ldots, v_n\}$. Then*

(i) $\operatorname{tr}(A^2) = 2|E(G)|$
(ii) $\operatorname{tr}(A^3) = 6c_3(G)$

where $c_3(G)$ denotes the number of triangles in G.

Proof. We know that $(A^m)_{ij}$ is the number of walks of length m from v_i to v_j.

(i) Hence, the ith diagonal entry of A^2, viz. $(A^2)_{ii}$, is the number of walks of length 2 from v_i to itself. Any walk of length 2 from v_i to itself is of the form $v_i v_j v_i$, where v_j is a vertex adjacent to v_i.

Thus, the number of such walks is equal to the number of vertices adjacent to v_i, i.e. $\deg v_i$. Hence, $\mathrm{tr}(A^2) = \sum_{i=1}^{n} \deg v_i = 2|E(G)|$, by Handshaking Lemma.

(ii) Similarly, $(A^3)_{ii}$ is the number of walks of length 3 from v_i to itself. Any such walk is of the form $v_i v_j v_k v_i$, which implies that v_i, v_j, and v_k form a triangle in G. Moreover, each such triangle corresponds to two distinct walks from v_i to itself, when traversed in the two opposite directions. Thus, $(A^3)_{ii}$ is twice the number of triangles having v_i as one of its vertices. Therefore, $\mathrm{tr}(A^3)$ is $6c_3(G)$, since each triangle contains three vertices, each of which counts the triangle twice in the sum $\mathrm{tr}(A^3)$. $\qquad\square$

Exercise 11.2. With notation as above, prove that the ith diagonal entry of A^4 is

$$(A^4)_{ii} = 2c_4(v_i) + \sum_{j:\, v_j \sim v_i} \deg v_j + 2\binom{\deg v_i}{2}$$

where $c_4(v_i)$ denotes the number of cycles of length 4 containing the vertex v_i, and hence show that the total number of cycles of length 4 in G is

$$c_4(G) = \frac{1}{8}\,\mathrm{tr}\,A^4 - \frac{1}{4}\sum_{i=1}^{n}(\deg v_i)^2 + \frac{|E(G)|}{4}$$

$$= \frac{1}{8}\,\mathrm{tr}\,A^4 - \frac{1}{4}\sum_{uv \in E(G)}(\deg u + \deg v - 1)$$

$$= \frac{1}{8}\,\mathrm{tr}\,A^4 - \frac{|E(G)|}{4} - \frac{1}{2}\sum_{i=1}^{n}\binom{\deg v_i}{2}.$$

12   Incidence Matrices

Consider an (n, m)-graph G having vertex set $\{v_1, \ldots, v_n\}$ and edge set $\{e_1, \ldots, e_m\}$. The incidence matrix of G is the $n \times m$ matrix $B = B(G)$ whose (i, j)-entry is 1 if the vertex v_i is incident with the edge e_i, and 0 otherwise.

Example 12.1. The incidence matrix of the graph

is

$$B = \begin{bmatrix} 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

Each column of the incidence matrix corresponds to an edge of the graph, and the only non-zero entries in the column correspond to the end-vertices of the edge – thus, each column contains exactly two 1s. In a simple graph, there is at most one edge between a given pair of vertices, and hence no two columns of the incidence matrix can be equal. We therefore have the following observation.

Observation 12.2. *The incidence matrix of a (simple, undirected) graph is a $(0, 1)$-matrix in which every column has exactly two 1s, and no two columns are equal.*

13 Line Graphs

Let G be a graph with at least one edge. The line graph of G is the graph $\mathcal{L}(G)$ whose vertex set is the edge set of G, in which two vertices e and f are adjacent if and only if the edges e and f of G are adjacent.

Example 13.1. Fig. 2 shows a graph G with eight edges and and its line graph $\mathcal{L}(G)$.

(a) G

(b) $\mathcal{L}(G)$

Figure 2: A graph and its line graph

If u and v are edges joined by an edge e in G, then in $\mathcal{L}(G)$, the vertex e will be adjacent to all the vertices corresponding to the edges of G other than e that are incident with u and v (see Fig. 3). Thus, $\deg_{\mathcal{L}(G)} e = \deg_G u + \deg_G v - 2$.

Figure 3: Neighbourhood of a vertex in $\mathcal{L}(G)$

Theorem 13.2. *For any graph G of size $m \geq 1$, its line graph $\mathcal{L}(G)$ has order m and size* $\displaystyle\sum_{v \in V(G)} \binom{\deg_G v}{2}$.

Proof. By definition, the vertices of $\mathcal{L}(G)$ are the edges of G, and hence the order of $\mathcal{L}(G)$ is the size of G, m.

Now, let $e = uv$ be an edge of G. In $\mathcal{L}(G)$, e is a vertex, and it is adjacent to another vertex f if and only if f is an edge of G and is adjacent to e, i.e. f is an edge of G incident with one of the end vertices of e, namely u and v. Thus, the degree of the vertex e of $\mathcal{L}(G)$ is equal to the total number of edges that are incident with either u or v in G, except for the edge e itself.

Clearly, u is incident with to $\deg_G u - 1$ edges other than e, and v is incident with $\deg_G v - 1$ edges other than e. Thus, the degree of e in $\mathcal{L}(G)$ is $\deg_G u - 1 + \deg_G v - 1$.

By Handshaking Lemma, the size of $\mathcal{L}(G)$ is half the sum of its vertex

degrees, which is

$$\frac{1}{2} \sum_{uv \in E(G)} (\deg_G u - 1 + \deg_G v - 1).$$

As the summation is over the edges of G, each vertex v of G appears exactly $\deg v$ times in the above summation, which can therefore be written as

$$\frac{1}{2} \sum_{v \in V(G)} (\deg_G v)(\deg_G v - 1) = \sum_{v \in V(G)} \binom{\deg_G v}{2}. \qquad \Box$$

The adjacency matrix of the line graph of G can be computed from the incidence matrix of G, as shown in the following result.

Theorem 13.3. *If B is the incidence matrix of a graph G, then the adjacency matrix of its line graph $\mathcal{L}(G)$ is*

$$A(\mathcal{L}(G)) = B^T B - 2I$$

where I is the identity matrix of order $|E(G)|$.

Proof. Let G be an (n, m)-graph with edge set $E = \{e_1, \ldots, e_m\}$. The incidence matrix $B = B(G)$ is of order $n \times m$, and therefore $B^T B - 2I$ is of order $m \times m$.

Observe that the (i, j) entry of $B^T B$ is the dot product of the ith and j^{th} columns of B. As each column of B has exactly two non-zero entries, both equal to 1, the (i, i) entry of $B^T B$ is 2, and therefore the diagonal entries of $B^T B - 2I$ are all zero.

For $i \neq j$, the dot product of the ith and j^{th} columns of B will be 1 if the edges e_i and e_j are adjacent (i.e. have one vertex in common), and 0 otherwise – note that the dot product cannot be 2, as no two distinct columns of B can be equal. Thus, for $i \neq j$, the (i, j)-entry of $B^T B$, which is equal to the (i, j) entry of $B^T B - 2I$, is 1 if and only if the edges e_i and e_j are adjacent in G, or equivalently, the vertices e_i and e_j of $\mathcal{L}(G)$ are adjacent. Thus, $B^T B - 2I$ is the adjacency matrix of G. $\qquad \Box$

A graph G is said to be a line graph if it is the line graph of some graph H. Not every graph is a line graph, as shown by the following example.

Example 13.4. Consider the graph $G = K_{1,3}$, the star graph of order 4. Suppose G is the line graph of some graph H. Then H has four edges, say e_1, e_2, e_3, e_4, which are the four vertices of G. Suppose e_1 is the central vertex of G. Then, as the vertices e_2 and e_3 are adjacent to e_1 in G, the edge e_1 of H has one end-vertex in common with each of e_2 and e_3. Let u be the vertex of e_1 common with e_2 and v the vertex of e_1 common with e_3. Note that $u \neq v$, since e_2 and e_3 are not adjacent in G. Now, since e_4 is adjacent to e_1 in G, the edge e_4 of H has either u or v as an end-vertex. Then e_4 is adjacent to either e_2 or e_3 in G, which is not possible.

14 Blocks and Cutvertices

A vertex v of a graph G is a cutvertex if $G - v$ has more components than G. A connected graph is nonseparable or 2-connected if it has no cutvertices. A maximal nonseparable subgraph of a graph G is a block of G. A nonseparable is itself also called a block.

Theorem 14.1. *If G is a connected graph, and v is any vertex of G, then the following are equivalent:*

(i) *v is a cutvertex of G.*
(ii) *There exist vertices u and w of G, distinct from v, such that every u-w path passes through v.*
(iii) *There exists a partition of $V(G) - \{v\}$ into two non-empty subsets U and W such that for all $u \in U$ and $w \in W$, every u-w path passes through v.*

Proof. (i) $\implies$ (iii). Since v is a cutvertex, the graph $G - v$ is disconnected, i.e. it has two or more components. Let U be the set of all the

27

vertices in any one of the components, and let W be the set of all the remaining vertices of $G - v$. Clearly, $\{U, W\}$ is a partition of $V(G) - \{v\}$. Now, if $u \in U$ and $w \in W$, then u and w are in different components of $G - v$, which implies that any path from u to w must pass through v.

(iii) $\implies$ (ii) is obvious as the latter is a special case of the former.

(ii) $\implies$ (i). Consider the graph $G-v$. As every u-w path passes through v, none of them is present in $G - v$, and therefore $G - v$ is disconnected. Hence, v is a cutvertex of G. $\qquad\square$

A cutedge or bridge of a graph G is an edge e of G such that $G - e$ has more components than G. The following characterisation of bridges can be proved along similar lines to that of Theorem 14.1.

Theorem 14.2. *If G is a connected graph, and e is any edge of G, then the following are equivalent:*

(i) *e is a bridge of G.*
(ii) *e is not on any cycle of G.*
(iii) *There exist vertices u and w of G such that every u-w path contains e.*
(iv) *There exists a partition of $V(G)$ into two non-empty subsets U and W such that for all $u \in U$ and $w \in W$, every u-w path contains e.* $\qquad\square$

Theorem 14.3. *If G is a connected graph of order at least 3, then the following are equivalent:*

(i) *G is a block.*
(ii) *Every two vertices of G lie on a common cycle.*
(iii) *Every vertex and edge of G lie on a common cycle.*
(iv) *Every two edges of G lie on a common cycle.* $\qquad\square$

15   Connectivity

A set S of vertices of a connected graph G is a separating set or vertex cut of G if $G - S$ is disconnected or trivial (i.e. a graph of order 1).

The vertex connectivity (or connectivity) of G, denoted by $\kappa(G)$ (or κ) is the cardinality of a minimum separating set of G – i.e. the minimum number of vertices G whose removal results in a disconnected or trivial graph. Similarly, a disconnecting set of a connected graph G is a set S of edges of G such that $G - S$ is disconnected or trivial. The cardinality of a minimum disconnecting set of G is the edge connectivity of G, and is denoted by $\lambda(G)$ (or λ). The vertex connectivity and edge connectivity of a disconnected graph are defined to be 0.

Theorem 15.1. *For any graph G, $\kappa(G) \le \lambda(G) \le \delta(G)$.*

Proof. If $\delta(G) = 0$, then clearly, $\lambda(G) = 0$. If $\delta(G) \ge 1$, then disconnecting all the edges incident with a vertex of degree $\delta(G)$ disconnects G, and hence $\lambda(G) \le \delta(G)$.

   If G is disconnected, then $\kappa(G) = \lambda(G) = 0$. If $\lambda(G) = 1$, then G has a bridge, say e, and hence the removal of any one end-vertex of e results in a disconnected graph or K_1, hence $\kappa(G) = 1$.

   Next, suppose that G has $\lambda \ge 2$ edges whose removal disconnects it. Then the removal of $\lambda - 1$ of these edges results in a graph with a bridge $e = uv$. Each of these edges has at least one end-vertex distinct from u and v. From each edge, remove one such vertex. Then the edges are removed as well, and the resulting graph is either disconnected, in which case $\kappa < \lambda$, or else has uv as a bridge. Then, removal of u or v gives a disconnected or trivial graph. Hence, $\kappa \le \lambda$. $\square$

Theorem 15.2. *For all integers a, b, c, with $0 \le a \le b \le c$, there exists a graph G with $\kappa(G) = a$, $\lambda(G) = b$, and $\delta(G) = c$.* $\square$

   It is easy to see that $\kappa(K_n) = n - 1$ and $\kappa(K_{p,q}) = \min(p, q)$. The following theorem gives the connectivity of the hypercube.

Theorem 15.3. *For any $k \ge 0$, the connectivity of the hypercube Q_k is $\kappa(Q_k) = k$.*

Proof. As Q_k is k-regular, $\kappa(Q_k) \leq k$. We claim that every vertex cut of Q_k contains at least k vertices. We prove this claim by induction on k. For $k = 0$ or 1, it is obvious.

Suppose the claim holds for Q_{k-1}, and consider $G = Q_k$, $k \geq 2$. Recall that $Q_k \cong K_2 \times Q_{k-1}$. Thus G has two subgraphs G_1 and G_2, each isomorphic to Q_{k-1}, joined by a perfect matching M of G. Now, let S be any vertex cut of G. If both $G_1 - S$ and $G_2 - S$ are connected, then $G - S$ is also connected, unless S contains at least one end-vertex of every edge of the matching M. Then, $|S| \geq |M| = 2^{k-1} \geq k$, as $k \geq 2$.

Next, suppose that $G_1 - S$ is disconnected. Then $|S \cup V(G_1)| \geq k - 1 = \kappa(Q_{k-1})$ (by the induction hypothesis). If S contains no vertex of G_2, then, as G_2 is connected, and every vertex of $G_1 - S$ has a neighbour in G_2, $G - S$ is connected, which is a contradiction. Thus, S contains at least one vertex of G_2. Hence, $|S| \geq (k - 1) + 1 = k$, as required. $\qquad\square$

Corollary 15.4. *For any $k \geq 0$, the edge connectivity of the hypercube Q_k is $\lambda(Q_k) = k$.*

Proof. From Theorem 15.1, $k = \kappa(Q_k) \leq \lambda(Q_k) \leq \delta(Q_k) = k$. $\qquad\square$

Theorem 15.5. *If G is 3-regular, then $\kappa(G) = \lambda(G)$.*

Proof. Let S be a minimum vertex cut of G. We know that $\lambda(G) \geq \kappa(G) = |S|$. We will show that $\lambda(G) = \kappa(G)$ by constructing a disconnecting set of size $\kappa(G) = |S|$.

Let H_1 and H_2 be two components of $G - S$. Since S is a minimum vertex cut, every vertex in S has a neighbour in H_1 and a neighbour in H_2. For each vertex v of S that has no neighbour inside S, delete the edge from v to that subgraph H_1 or H_2 in which it has a unique neighbour. For each vertex u of S that has a neighbour in S, delete the edge from u to H_1. Then the resulting graph is disconnected, and hence $\lambda(G) = |S| = \kappa(G)$. $\qquad\square$

16 Covering and Independence

A vertex v and an edge e of a graph G cover each other if v is incident on e. A vertex cover is a set of vertices of that cover all the edges. An edge cover is a set of edges that cover all vertices.

A vertex (or edge) cover is minimal if no proper subset of itself is a vertex (or edge) cover. It is minimum if it has the least cardinality among all vertex (or edge) covers of the graph. The cardinality of a minimum vertex cover of G is the vertex covering number of G, denoted by $\alpha_0(G)$, and the cardinality of a minimum edge cover of G is the edge covering number of G, denoted by $\alpha_1(G)$.

A set of vertices or a set of edges of G is independent if no two of its elements are adjacent. An independent set of vertices (or edges) is maximal if it is not properly contained in any independent set, and is maximum if it has the largest cardinality among all independent sets of vertices (or edges). The vertex independence number of G, denoted by $\beta_0(G)$, is the cardinality of a maximum independent set of vertices of G. The edge independence number of G, denoted by $\beta_1(G)$, is the cardinality of a maximum independent set of edges of G.

Example 16.1. The values of the parameters α_0, β_0, α_1, and β_1 for some families of graphs are listed below.

G	α_0	β_0	α_1	β_1
K_n	$n-1$	1	$\lceil \frac{n}{2} \rceil$	$\lfloor \frac{n}{2} \rfloor$
$K_{p,q}$	$\min(p,q)$	$\max(p,q)$	$\max(p,q)$	$\min(p,q)$
C_n	$\lceil \frac{n}{2} \rceil$	$\lfloor \frac{n}{2} \rfloor$	$\lfloor \frac{n}{2} \rfloor$	$\lceil \frac{n}{2} \rceil$
P_n	$\lfloor \frac{n}{2} \rfloor$	$\lceil \frac{n}{2} \rceil$	$\lceil \frac{n}{2} \rceil$	$\lfloor \frac{n}{2} \rfloor$
Q_k	$2^{k-1} = \frac{n}{2}$	$2^{k-1} = \frac{n}{2}$	$2^{k-1} = \frac{n}{2}$	$2^{k-1} = \frac{n}{2}$

Exercise 16.1. Justify the values of the parameters given in Theorem 16.1.

Exercise 16.2. Prove that a set S of vertices of G is independent if and only if $V(G) \setminus S$ is a vertex cover of G.

Gallai's theorem

Notice that for each graph G in Theorem 16.1, $\alpha_0(G) + \beta_0(G) = \alpha_1(G) + \beta_1(G) = n$, the order of G. This is true in general for all graphs, and this fact is known as Gallai's theorem.

Theorem 16.2 (Gallai). *For any graph G of order n,*

$$\alpha_0(G) + \beta_0(G) = \alpha_(G) + \beta_1(G) = n.$$

Proof. Let M_0 be a maximum set of independent vertices of G. Then $\beta_0 = |M_0|$, and $V \setminus M_0$ is a vertex cover. Hence, $\alpha_0 \le |V \setminus M_0| = n - \beta_0$. Let N_0 be a minimum cover of G. Then $\alpha_0 = |N_0|$, and $V \setminus N_0$ is independent. Hence, $\beta_0 \ge |V \setminus N_0| = n - \alpha_0$. Thus, $\alpha_0 + \beta_0 = n$.

Now, let M_1 be a maximum set of independent edges. Form an edge cover Y of G by adding to M_1 one edge incident with each vertex not covered by M_1. Then $|Y| = n - |M_1| = n - \beta_1$, which implies that $n - \beta_1 \ge \alpha_1$, i.e. $\alpha_1 + \beta_1 \le n$.

Next, let N_1 be a minimum edge cover of G. Then an independent set of edges is obtained by taking one edge of each component of the induced graph $\langle N_1 \rangle$. Hence, $\beta_1 \ge n - |N_1| = n - \alpha_1$, which implies that $\alpha_1 + \beta_1 \ge n$. Thus, $\alpha_1 + \beta_1 = n$. □

17 Matching

A matching of G is a set of independent edges of G. A vertex is saturated by a matching M (it is M-saturated) if it is incident to some edge of M, and otherwise it is unsaturated by M (it is M-unsaturated). A matching is

(i) maximal if it is not properly contained in any other matching.
(ii) maximum if it has greatest cardinality among all matchings.
(iii) perfect if it saturates all vertices.

A path of G is M-alternating if its edges are alternately from M and $E(G) \setminus M$. An M-augmenting path is an M-alternating path whose end-vertices are M-unsaturated.

Note. If P is an M-augmenting path, we can obtain a matching of cardinality $|M| + 1$ by replacing the edges of P in M by the edges of P not in M.

Recall that the symmetric difference of two sets A and B is the set $A \triangle B = (A \setminus B) \cup (B \setminus A)$. If M and M' are two matchings of a graph G, then the symmetric difference of M and M' (also denoted $M \triangle M'$) is the graph induced by the set $M \triangle M'$.

Lemma 17.1. *Every component of the symmetric difference of two matchings is a path or an even cycle.*

Proof. Let $F = M \triangle M'$. As M and M' are matchings, every vertex has at most one incident edge from each of them. Hence, $\Delta(F) \leq 2$. As the edges must be alternately from $M \setminus M'$ and $M' \setminus M$, each cycle is of even length. □

Theorem 17.2 (Berge). *A matching M of G is maximum if and only if G has no M-augmenting path.*

Proof. If G has an M-augmenting path P, then the matching obtained from M by removing the edges of P that are in M and adding those edges of P that are not in M has cardinality $|M| + 1$, which implies that M cannot be a maximum matching. Thus, if M is a maximum matching, G has no M-augmenting path.

Conversely, suppose that M is not a maximum matching in G. Then G has a matching M', with $|M'| > |M|$. Let $F = M \triangle M'$. Then, by Theorem 17.1, every component of F is a path or an even cycle, and

each even cycle contains an equal number of edges from M and M'. Hence, as $|M'| > |M|$, at least one component of F must be path, which is an M-augmenting path of G. □

Hall's matching condition

Let G be a bipartite graph with bipartition (V_1, V_2). If M is a matching of G that saturates V_1 (i.e. saturates all vertices in V_1), then observe that for every subset $S \subseteq V_1$, $|N_G(S)| \geq |S|$, where $N_G(S)$ is the set of all vertices of G that have at least one neighbour in S – equivalently, it is the union of the neighbourhoods of all the vertices in S.

If G is a bipartite graph, then a partite set X of G is said to satisfy Hall's condition if $|N_G(S)| \geq |S|$ for all $S \subseteq X$.

Theorem 17.3 (Hall's Theorem). *A bipartite graph G with bipartition (V_1, V_2) has a matching that saturates V_1 if and only if V_1 satisfies Hall's condition.*

Proof. If G has a matching that saturates V_1, then distinct vertices u and v in V_1 have distinct neighbours via the edges of the matching incident on them. Thus, for any $S \subseteq V_1$, $|N_G(S)| \geq |S|$.

For the converse, suppose that G has a maximum matching M that does not saturate V_1. We will show that V_1 does not satisfy Hall's condition, by constructing a set S for which $|N_G(S)| < |S|$.

Let u be an M-unsaturated vertex in V_1. Let S be the vertices in V_1 reachable by an M-alternating path, and let T be the vertices in V_2 reachable by an M-alternating path. Note that $u \in S$.
Claim: M matches T with $S \setminus \{u\}$.

First, observe that any M-alternating path from u reaches V_2 along edges not in M and returns to V_1 along edges in M. Thus, each vertex of $S \setminus \{u\}$ is reached by an edge in M from a vertex in T. Every vertex in T must be M-saturated, for otherwise, G would have an M-augmenting path, which is not possible as M is a maximum matching. Therefore, any

M-alternating path from u to a vertex $y \in T$ can be extended to a vertex in S via some edge of M. These edges define a bijection between T and $S \setminus \{u\}$.

Thus, $|T| = |S| - 1$, and $T \subseteq N_G(S)$. We show that $T = N(S)$. Suppose, to the contrary, that some vertex $Y \in V_2 \setminus T$ has a neighbour $x \in S$. The edge xy cannot be in M, as u is M-unsaturated, and the other vertices in S are matched to T by M. Hence, an M-alternating path from u to x can be extended to y by the edge xy, which contradicts the assumption that $y \notin T$. Therefore, y cannot have such a neighbour $x \in S$.

Now, as $T = N_G(S)$, $|N_G(S)| = |T| = |S| - 1 < |S|$, and hence V_1 does not satisfy Hall's condition. $\qquad\square$

Corollary 17.4. *For each positive integer k, every k-regular bipartite graph has a perfect matching.*

Proof. Let G be a k-regular bipartite graph with bipartition (V_1, V_2). Then $|V_1| = |V_2|$. Hence, a maximum matching is a perfect matching if and only if it saturates V_1. We show this by proving that V_1 satisfies Hall's matching condition.

Consider any $S \subseteq V_1$. Then the induced subgraph $H = \langle S \cup N_G(S) \rangle$ is a bipartite subgraph in which every vertex of S has degree k. Hence, $k|S| = \sum_{v \in N_G(S)} \deg_H v \leq k|N_G(S)|$, which implies that $|N_G(S)| \geq |S|$. That is, V_1 satisfies Hall's condition, as required. $\qquad\square$

18 Graph Colouring

A *k-colouring* of a graph G, where k is a non-negative integer, is a function $c : V(G) \to S$, where $|S| = k$. The elements of S are colours, and the set of all vertices of G with one colour is a colour class. Henceforth, we will consider $S = \{1, 2, \ldots, k\}$. A k-colouring is proper if adjacent vertices receive distinct colours (note that if $c(v) = i$, then we say that the vertex v receives or is assigned the colour i). G is *k-colourable* if it has a

proper k-colouring. The chromatic number of G, denoted by $\chi(G)$, is the least k such that G is k-colourable. If $\chi(G) = k$, then G is k-chromatic, and a k-colouring is optimal.

Exercise 18.1. Prove the following:

1. $\chi(K_n) = n$.
2. $\chi(C_n) = \begin{cases} 2, & n \text{ is even} \\ 3, & n \text{ is odd}. \end{cases}$
3. $\chi(G) = 2$ if and only if G is a bipartite graph with at least one edge.
4. If H is any subgraph of G, then $\chi(G) \geq \chi(H)$.

A clique of G is a maximal complete subgraph of G. The order of the largest clique of G is the clique number of G, denoted by $\omega(G)$.

Theorem 18.1. *For any graph G of order n,*

$$\max\left(\omega(G), \frac{n}{\beta_0(G)}\right) \leq \chi(G) \leq \Delta(G) + 1. \tag{3}$$

Proof. Since the clique of order $\omega(G)$ is a subgraph with chromatic number $\omega(G)$, $\chi(G) \geq \omega(G)$. As the colour classes in a proper $\chi(G)$-colouring of G partition $V(G)$ into $\chi(G)$ sets, each of which is independent and hence has at most $\beta_0(G)$ vertices, $n = |V(G)| \leq \chi(G)\beta_0(G)$, and hence $\chi(G) \geq \frac{n}{\beta_0(G)}$.

Now, we prove that $\chi(G) \leq \Delta(G) + 1$, by induction on n. The claim obviously holds for $n = 1$ ($\Delta(G) = 0$, $\chi(G) = 1$).

Suppose that the result is true for any graph of order $n - 1$, and consider a graph G of order n, $n > 1$. Let v be any vertex of G. Then $\Delta(G - v) \leq \Delta(G)$, and hence, by the induction hypothesis, $G - v$ is $(\Delta(G) + 1)$-colourable. Consider such a colouring. Now, $\deg_G v \leq \Delta(G)$, and therefore at least one of the $\Delta(G) + 1$ colours is not assigned to any neighbour of v in the colouring of $G - v$. Assign one such colour to v to extend the colouring of $G - v$ to a proper $(\Delta(G) + 1)$-colouring of G. $\square$

Theorem 18.2. *The chromatic number of the Cartesian product of two graphs G and H is $\chi(G \times H) = \max(\chi(G), \chi(H))$.*

Proof. Since $G \times H$ has subgraphs isomorphic to G and H, $\chi(G \times H) \geq \max(\chi(G), \chi(H))$.

Let $k = \max(\chi(G), \chi(H))$, and let c_1 and c_2 be optimal colourings of G and H respectively, with colours $\{1, \ldots, k\}$. Define a colouring c of $G \times H$ by $c(u, v) = c(u) + c(v)$ modulo k, for $(u, v) \in V(G \times H)$. Clearly, c is a k-colouring of $G \times H$. To see that c is proper, suppose $(u_1, v_1) \sim_{G \times H} (u_2, v_2)$. Then $c(u_1, v_1) - c(u_2, v_2) = [c(u_1) - c(u_2)] + [c(v_1) - c(v_2)]$. One of the two bracketed terms is 0 and the other is non-zero modulo k. □

Exercise 18.2.   1. Prove that the chromatic number of any graph G is the maximum of the chromatic numbers of its

(i) components.
(ii) blocks.

2. Show that for any two graphs G and H,

(i) $\chi(G \cup H) = \max(\chi(G), \chi(H))$.
(ii) $\chi(G + H) = \chi(G) + \chi(H)$.

3. Let $G = K_2 + C_5$. Compute $\omega(G)$ and $\chi(G)$.
4. Let $G = K_p + C_{2r+1}$, where $r \geq 2$. Compute $\omega(G)$ and $\chi(G)$.
5. Suppose that G is a graph such that $\chi(G) = \omega(G) + 1$. Recursively define H_k as $H_1 = G$, $H_k = H_{k-1} + G$, $k > 1$ (i.e. H_k is the join of k copies of G). Prove that $\chi(H_k) = \omega(H_k) + k$.

Chromatic polynomials

For any non-negative integer k, we denote the number of proper k-colourings of the graph G by $p_\chi(G; k)$. We shall see that $p_\chi(G; k)$ can be expressed as a polynomial in k.

Exercise 18.3. By combinatorial arguments, prove the following:

1. $p_\chi(K_n; k) = k(k-1)\cdots(k-n+1)$.
2. $p_\chi(\overline{K_n}; k) = k^n$.
3. $p_\chi(P_n; k) = k(k-1)^{n-1}$.
4. $p_\chi(C_4; k) = k^4 - 4k^3 + 6k^2 - 4k + k = (k-1)^4 + (k-1)$. **Hint:** Use the principle of inclusion and exclusion.

Consider a partition of $V(G)$ into independent sets. Then any assignment of colours from $\{1, \ldots, k\}$ to G that assign distinct colours for vertices in different parts of the partition, such that all vertices in the same part receive the same colour, is a proper k-colouring of G. Conversely, any proper k-colouring of G induces such a partition of G into independent sets that are precisely the colour classes. If the number of parts in the partition is r, then the number of different such colourings possible is $k(k-1)\cdots(k-r+1)$. Thus, if $\pi_r(G)$ is the number of ways to partition $V(G)$ into r independent sets, then

$$p_\chi(G; k) = \sum_{r=1}^{n} \pi_r(G) k(k-1) \cdots (k-r+1).$$

Note that this is a polynomial in k. If n is the order of G, then $\pi_n(G) = 1$, which implies that $p_\chi(G; k)$ is a monic polynomial in k having degree n.

The chromatic polynomial of G with indeterminate x is the unique monic polynomial in x of degree n whose value at $x = k$ is $p_\chi(G; k)$, for every non-negative integer k. We denote it by $p_\chi(G; x)$.

The contraction of an edge e of G is the operation of removing e and replacing its end-vertices by a new single vertex that is incident with all the edges that are adjacent to e in G. The resulting graph is denoted by $G \cdot e$. Now, we give a recurrence relation for computing the chromatic polynomial of G in terms of edge contraction and edge deletion.

Theorem 18.3. *If e is an edge of a graph G, then*

$$p_\chi(G; x) = p_\chi(G - e; x) - p_\chi(G \cdot e; x).$$

Proof. Let $e = uv$. Any proper k-colouring of $G - e$ assigns either the same colour or two different colours to u and v. Any colouring of the first kind defines a proper k-colouring of $G \cdot e$, where the new vertex of $G \cdot e$ receives the same colour as u and v, and any vertex receives the same colours as in $G - e$. Any colouring of $G \cdot e$ of the second kind is naturally a proper k-colouring of G, as it assigns different colours to u and v, the end-vertices of e. Thus, $p_\chi(G-e; x) = p_\chi(G \cdot e; x) + p_\chi(G; x)$. $\quad \square$

Theorem 18.4 (Whitney). *For any graph G of order n, the chromatic polynomial $p_\chi(G; x)$ is a monic polynomial of degree n, with integer coefficients alternating in sign, having $-m$ as the coefficient of x^{n-1}.*

Proof. Let m be the size of G. We prove the result by induction on m. If $m = 0$, $G \cong \overline{K_n}$, and hence $p_\chi(G; x) = x^n$, so the result holds.

Assume, for the sake of induction, that the result holds for any graph of size $m - 1$ and let G be a graph of order n and size m, where $m \geq 1$. As $G - e$ and $G \cdot e$ are each of size $m - 1$, by the induction hypothesis,

$$p_\chi(G - e; x) = x^n - (m-1)x^{n-1} + a_2 x^{n-2} - \cdots + (-1)^r a_r x^{n-r} + \cdots$$
$$p_\chi(G \cdot e; x) = x^{n-1} - (m-1)x^{n-2} + b_2 x^{n-2} - \cdots + (-1)^r b_r x^{n-r} + \cdots$$

for some non-negative integers $a_2, a_3, \ldots$ and $b_2, b_3, \ldots$.

Now, by Theorem 18.3, the chromatic polynomial of G is given by

$$p_\chi(G; x) = x^n - [(m-1) + 1]x^{n-1} + (a_2 + m - 1)x^{n-2} -$$
$$\cdots + (-1)^r (a_r + b_r)x^{n-r} + \cdots$$
$$= x^n - mx^{n-1} + (a_2 + m - 1)x^{n-2} - \cdots + (-1)^r (a_r + b_r)x^{n-r} + \cdots$$

which proves the result. $\quad \square$

Exercise 18.4. Using Theorem 18.3, prove by mathematical induction that

1. $p_\chi(C_n; x) = (x-1)^n + (-1)^n(x-1)$ for any $n \geq 3$.
2. $p_\chi(T; x) = x(x-1)^{n-1}$ for any tree T of order n.
